

Fundamental incompatibility with ray and Python*

- Python forces me to install 3.14.6 (or latest version)
- Ray only goes up to 3.12

*Solution Found from [manual installation steps for older versions of WSL](#):

- Use WSL (Windows Subsystem for Linux) as a remedy to load an older version of Python.
- First, type "dism.exe /online /enable-feature /featurename:Microsoft-Windows-Subsystem-Linux /all /norestart" to enable WSL.
- Type "dism.exe /online /enable-feature /featurename:VirtualMachinePlatform /all /norestart" to enable the Virtual Machine feature.
- Type "wsl.exe --install" in Powershell (Run as Administrator if possible) as this downloads the Linux kernel update package.
- Type "wsl --set-default-version 2" to set WSL 2 as the default version.
- Install the Linux distribution of choice (I chose [Ubuntu](#)).
- Open WSL on your computer.
- Set username and password.

The following steps are roughly based off of [this tutorial](#):

- Type "sudo apt update && sudo apt upgrade -y" (This updates your package list).
- Type "sudo apt install software-properties-common -y" (This installs the software properties common package).
- Type "sudo apt autoremove" (This removes the unnecessary packages).
- Type "sudo add-apt-repository ppa:deadsnakes/ppa" (This installs the Deadsnakes PPA.)
- Type "sudo apt update" (This updates the package list again.)
- Type "sudo apt install python3.11 python3.11-venv python3.11-dev -y" (This installs an older version of Python, though you can install whatever version of Python you want)
- Check if the version of Python is installed with "python3.11 --version".

Steps taken from [this tutorial](#):

- You'll also need to install uv with "curl -LsSf https://astral.sh/uv/install.sh | sh"
- You'll need to create the virtual environment for the project as well with "uv init your-project-name"
- Navigate to your-project-name with "cd your-project-name"
- Now create the virtual environment with "uv venv"
- This SHOULD create a ".venv" folder
- Now replace the main.py and pyproject.toml files with the files found in the GitHub.
-
- Another important thing to do is generate an API key so your AI agent can communicate/respond to prompts.
- Go to <https://aistudio.google.com/api-keys>
- Click "Create New Key", name the key, and copy said key.
- Create an ".env" file and store the API key as "GEMINI_API_KEY=your-API-key-here".

- Add the .env file to the .gitignore along with the .venv folder.
-
- Your file setup should (roughly) look like this:
